

**1 Jump Force: Democratizing Actionable Rehabilitation**

**2**  
**3 JOSHUA SCHMIDT**, Cornell Tech, USA  
**4**

**5** Jump Force is a novel data collection device for automating and standardizing the vertical jump Return to Play protocol. This protocol  
**6** is used today to assess the state of an athlete's rehabilitation when recovering from knee injuries, one of the most common injury  
**7** types in the NCAA. This wearable device consists of an array of sensors used to analyze the angle, speed and other characteristics of  
**8** vertical jumps, using this data to estimate the amount of force exerted over time. There is further discussion as to how to make this  
**9** data more accessible, consistent and actionable, to reinvent the protocol.  
**10**

**19**

**20** **1 INTRODUCTION**  
**21**

**22** According to the most recent estimates for 2021, among the more than 500,000 college athletes who competed in the  
**23** NCAA there were more than 210,000 reported injuries, and more than 90% of participants stated they had some form of  
**24** injury [4]. Some high profile players, such as Stanley Doughty (defensive lineman at the University of South Carolina)  
**25** and Marcus Lattimore, also from USC, were forced to quit their sports due to serious injuries [4]. These injuries vary  
**26** widely in scope and areas of the body affected. The most common are head and ankle injuries [2], with an average of  
**27** 10,560 concussions [15] and 47,250 ankle injuries [13] reported over the 2009-2010 and 2013-2014 seasons. Knee related  
**28** injuries were the third most common, with 8,470 reported over the 2013-2014 season [1, 15]. These numbers are getting  
**29** worse, not better, as athletes take more risks and there is more inclusivity and competition in sports. Injuries overall are  
**30** up 4.7% in the 2021-2022 season compared to the 2013-2014 season [4, 15]. There are even instances of injuries that are  
**31** fatal.  
**32**

**33** The number of injuries per year is staggering, and it is troubling that the problem is getting worse, not better.  
**34** However, with every major problem there are opportunities for novel solutions. Instead of looking at the all sports  
**35** injuries or even all injuries in a given sport, it is necessary to reduce scope to an actionable level. In this paper, we  
**36** will be exploring specifically knee-related injuries, and how novel data-collecting methods can help with preventing  
**37** repeated injuries. We will focus on the return-to-play protocol, a system physical therapists use to gauge injury recovery.  
**38** We will propose a novel data collection system, *Jump Force*, that uses a smart knee pad to automate this protocol, and  
**39** discuss future areas for work.

### 53      1.1 Return to Play Protocol

54  
 55      The term *Return to Play Protocol* is used loosely in the sports industry and varies from sport to sport. It sometimes even  
 56      varies between trained professionals. There were some recent attempts at standardizing the protocols by sport [9], but  
 57      these have not caught on yet. The *Return to Play Protocol* is a test that trained physical therapists conduct to determine  
 58      if an athlete is fit to play again. Typically the assessment includes testing muscular force by comparing complimentary  
 59      muscle groups, i.e. left hand to right hand, right arm to left arm, right knee to left knee. Practitioners would assess  
 60      functional gait abnormalities as the patient performs standard motions (wrist rotation, arm curl, jump) [9].

61  
 62      This procedure is largely qualitative, comparing a healthy side to an injured side, and does not have a set baseline for  
 63      expected results [9]. There is also typically no standard form of data collection, though there is some research in that  
 64      field as well [5]. Another limitation of these procedures is they often need to be completed in a sterile environment, i.e.  
 65      off the playing field, making it less accurate accessible to athletes who want to play as soon as possible [9]. Additionally,  
 66      due to the limited time span of these procedures (on average 5-10 minutes), they are unable to measure fatigue and  
 67      endurance accurately [5]. Any enhancement to the *Return to Play Protocol* would need to address most if not all of these  
 68      issues, while making it more accessible to those who should be tested.

### 71      1.2 Vertical Jump Methods

72  
 73      The *Return to Play Protocol* variant we will be focusing on is the *Vertical Jump* method. This variant is the most widely  
 74      used for knee-related injuries due to its simplicity [12]. The method assesses the strength of the patient's glutes, quads,  
 75      hamstring's and calves, and assesses their athletic power [12]. There are several different Vertical Jump test methods,  
 76      including chalk on wall (jumping and marking how high you get), Vertec (a specialized vertical jump tester), and a  
 77      pressure / force plate. In this experiment we are using a force plate test as our baseline [12].

78  
 79      In the vertical jump, there are several different events. These include standing, crouching, takeoff, peak height, and  
 80      landing [12]. These correspond to different stages: before the jump, descend, accelerate up, flight to peak, flight to  
 81      landing, and after the jump [12]. See the figure 1 below.

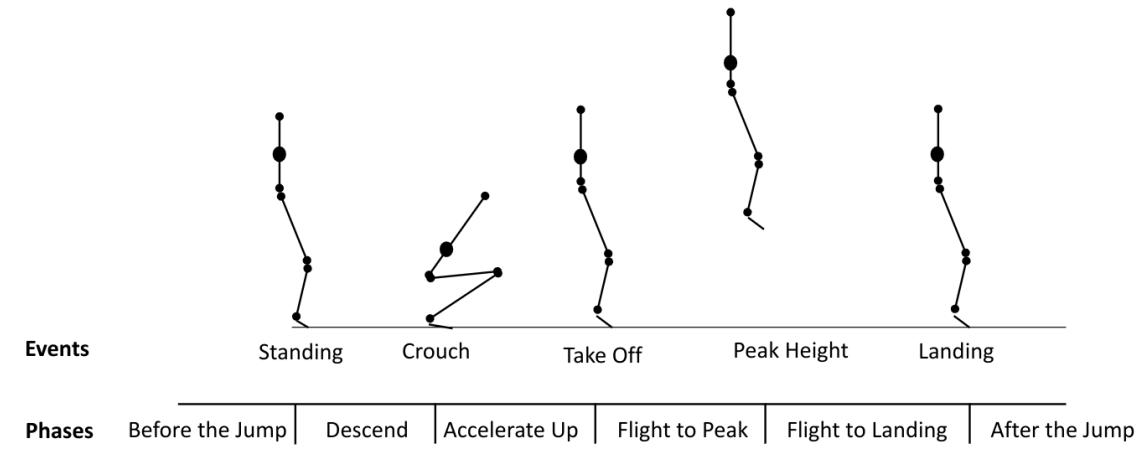

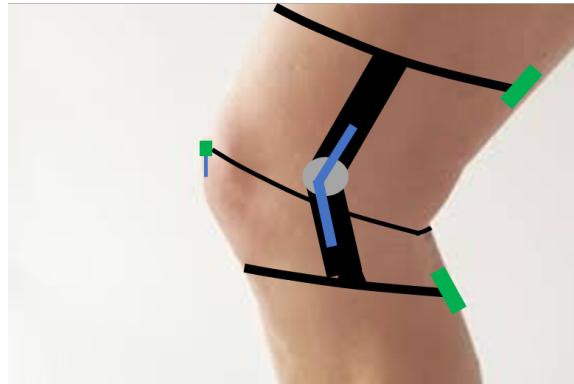

Fig. 1. Vertical Jump Phases.

105 In this protocol, we are most concerned with how the force created from the descend and accelerate up events  
 106 translates to the maximum height of the jump. Athletes that have equal force to height ratios before and after injuries,  
 107 after several subsequent tests, are fit to return to play. Ideally, we will compare the athletes to a baseline that they  
 108 recorded before their injury occurred, and one that is recent enough to reflect their athletic ability.  
 109

## 110 2 DESIGN

111 When initially designing *Jump Force*, the goal was to create a device that contains enough sensors to fully explain the  
 112 motion of the jump. We wanted the device to be small enough to fit in a standard knee pad, and not require any external  
 113 specialized equipment. To determine the height of the jump, we opted for camera vision, using the camera included in  
 114 your smartphone. The types of sensors we added to analyze the motion of the jump include flex sensors, hall effect  
 115 sensors, and accelerometers. Below is a figure 2 of the initial design.  
 116

### 135 2.1 Sensors

136 There were two types of *Spectra* flex sensors used, single-sided and double sided, in pairs of two, one of both sides of the  
 137 kneecap. This creates a matrix of four flex sensors. The *US1881* hall effect sensor was placed at the top of the knee pad,  
 138 with a neodymium magnet placed on the opposite end of the knee pad. The distance between the magnet and hall effect  
 139 sensor is a constant, at 10.5cm, and with the distance to the rotation axis also known (5.25cm), it is straightforward to  
 140 determine the angle of the knee at any given time. The flex sensors are used individually to calculate the current angle.  
 141 Once calibrated, they generate a voltage when deformed which linearly correlates to the amount of deformation. This  
 142 information can be used to find the current bend angle of the knee during the jump.  
 143

144 One goal of this experiment was to find the combination of sensors that would show the most accurate representation  
 145 of the angle of the knee over time, and how that correlates to force exerted over time. That is why we included both  
 146 flex sensors and hall effect sensors. There was only one hall effect sensor in the final design, but in the initial there  
 147 were two for redundancy. The reason why we excluded one of the hall effect sensors was when testing we saw that it  
 148 was not necessary. The hall effect sensors produced near identical results. However, we found that the flex sensors  
 149 were not nearly as accurate, producing 8% – 15% deviations in values between trials. This was after calibration steps.  
 150 Aggregating the results from multiple flex sensors did help to smooth out this noise, lowering the deviation to 4% – 8%.  
 151

## 157      **2.2 Hall Effect Sensor Placement**

158  
 159 After deciding to use only a single Hall Effect sensor, the next question was how it would be mounted. At first, it was  
 160 mounted in the front of the knee pad, so the sensor would be closer to the microcontroller collecting the data. However  
 161 after conducting preliminary tests we noticed that the amount of mass between the sensor and magnet adds too much  
 162 noise to the signal. Instead placing the sensor on the inside of the kneepad enables the sensor and magnet to have a  
 163 direct line of sight, and therefore has a much cleaner signal. Compared to the old configuration, placing the Hall Effect  
 164 sensor on the back of the knee pad increased accuracy by 68%.  
 165

## 166      **2.3 Microcontroller**

167 In order to collect all of this sensor data, we used a Heltec ESP-32 WiFi v2 microcontroller [7]. This controller uses a  
 168 dual core 240MHz Tensilica LX6 chip with onboard WiFi and Bluetooth 5, and has an onboard 12-bit ADC. 47.5kΩ  
 169 ballast resistors are added to the circuit before connecting the flex sensors to the ADC. In addition to the flex sensors  
 170 and hall effect sensor, the microcontroller is connected to a 9DoF BNO055 IMU [8]. This IMU is used for collecting  
 171 acceleration data to more directly correlate the jump motion to force exerted, when doing the *Return to Play Protocol*.  
 172

173 All of this sensor data is sampled at 120Hz. This sampling rate was chosen because it is twice the frame rate of  
 174 the camera on modern-day smartphones, which is used for getting the height of the jump. Several filters were used  
 175 to process the data before it left the microcontroller. These filters include a bandpass filter for the flex sensors and a  
 176 lowpass filter for the hall effect sensor. Each of the flex sensor filters and hall effect sensor filter needed to be individually  
 177 calibrated experimentally. These filters helped increase the accuracy of the sensor system dramatically, as the initial  
 178 data was too noisy to be useful. Once the basic filtering is done it is ready to be processed.  
 179

## 180      **2.4 Smartphone Connection**

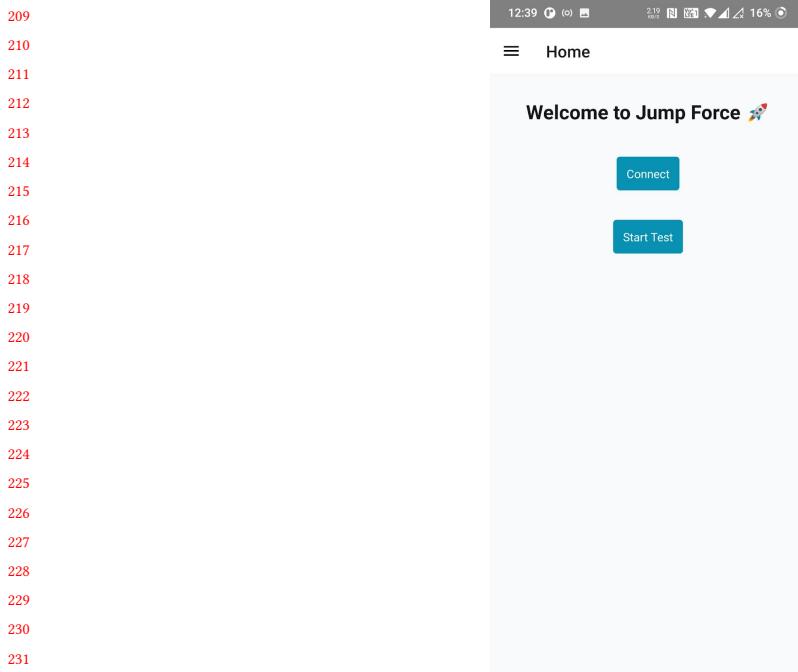

181 The Bluetooth protocol is used to get the data off of the microcontroller. Users can connect to the kneepad (the  
 182 microcontroller) using a custom mobile app, and as soon as they connect they can start the recording process. A  
 183 screenshot of the app is shown in the below figures 3a.

184 The mobile app is written using React Native [10] and Expo [6], allowing fast iteration of designs and user interface.  
 185 NativeBase was the component library used to allow for native styling on both Android and iOS devices [11].  
 186

## 187      **2.5 Initial Cloud Processing**

188 After you finish recording both the video file and kneepad data is uploaded to an AWS S3 bucket. The kneepad data is  
 189 saved as a csv file, with all of timestamps recorded in ISO8601 format. Uploading triggers an AWS Lambda function to  
 190 analyze the video file. This function uses the OpenCV python library [3] to track the movement of green markers on  
 191 the kneepad. Using the known distance between the camera and the kneepad of 2.5 meters, the function calculates the  
 192 height at all of the timestamps in the kneepad data file. Since the kneepad is sampling at twice the speed of the camera,  
 193 the height information for a given frame is generally mapped to two samples. After this lambda function is finished, the  
 194 data is saved to a concatenated csv file in S3 containing all of the kneepad fields plus the height at that time.  
 195

196 Saving the concatenated csv file triggers a second lambda function, the data processing function. This function  
 197 analyzes the flex sensor, hall effect, IMU and height data, and correlates it with the ground-truth force data, the data  
 198 from the force plate. This force plate data is collected on a laptop using a simple python script with a serial logger,  
 199 which generates a csv file and saves it to the same S3 bucket. The force plate data is sampled at 9600 baud or 9.6kHz,  
 200

(a) Connect Screen.

which is more than fast enough to support the kneepad data rate of 120Hz. The force plate is from Vernier, and you can find technical specifications here [14]. A picture of the force plate is shown below 4.

Fig. 4. Force Plate.

**261      2.6 Force Correlation Processing**

**262**  
**263** The data processing function finds the angle the knee is bent in at any given time, and calculates the bend rate in the  
**264** *descend* and *accelerate up* phases. With this data, we are able to calculate the correlation between bend rate and force  
**265** exerted, and between initial acceleration and force exerted. This data can be found in the Results [4](#) section. We were  
**266** also able to break out the bend rate correlations into data from each sensor type (hall effect and flex sensors). Jump  
**267** height and acceleration data are also added as normalization factors for the knee angle, to test if this improves the  
**268** correlation between the force exerted and knee angle.  
**269**

**270**  
**271** **3 EXPERIMENTAL PROCEDURE**  
**272**

**273** The Experimental Procedure is as follows. We record ten jumps at a time, with participants told to try to make the jump  
**274** height and style as consistent as possible. We told participants to try to only use their knees to jump, as opposed to  
**275** their ankles or muscle groups besides their quads.  
**276**

**277**  
**278** **3.1 Questionnaire**  
**279**

**280** We have participants fill out a simple questionnaire containing questions such as how many times and for what duration  
**281** the participant exercises per week, if they are involved in any sports and if so, which ones, how they would rate their  
**282** athletic abilities, the longest distance they are able to run, and how high do they think they are able to jump. All  
**283** of this data is used to control for different athletic abilities in the experimental results, and gain a more qualitative  
**284** understanding of our participants.  
**285**

**286**  
**287** **3.2 Procedure**  
**288**

**289** Participants do the set of ten jumps three times, for a total of 30 jumps, with a one minute break in between each set.  
**290** This makes the total time for the experiment less than 10 minutes per participant, from start to finish. The jumps are  
**291** conducted in a controlled environment indoors, on a force plate, when wearing the Jump Force kneepad. This is the  
**292** only environment in which we are able to conduct this experiment, because the force plate would be less accurate on an  
**293** actual soccer field. After doing the jumps they complete the exit survey as described here [3.1](#), and additionally submit  
**294** feedback as to the quality of the experiment.  
**295**

**296**  
**297** **3.3 Prototype**  
**298**

**299** The prototype is shown in the figure below [5](#). In the center of the image you can see the matrix of flex sensors. The hall  
**300** effect sensor is positioned on the back of the kneepad so it is not currently visible. Near the top of the kneepad you can  
**301** also see the IMU. The green dots are the trackers for the camera vision system.  
**302**

**303** Most of the components were either hot-glued or sewn onto the kneepad. The flex sensors were only fastened at the  
**304** ends so they could stretch and compress as the user goes through the jumping motion. The microcontroller is visible  
**305** near the top of the kneepad, and includes a status LED for power and an OLED screen containing basic diagnostic  
**306** data (logging information, if the device is connected via Bluetooth, etc). The microcontroller is powered by a 1000mAh  
**307** battery, fastened behind the board, and charges the via micro-USB debugging port [6](#).

## 365 4 RESULTS

366 In the experiment we recorded samples from four participants over the span of two days. The participants completed the  
 367 experimental procedure, as described in detail here 3.2. Below are the questionnaire results from each of the participants  
 368 1.

371 Table 1. Questionnaire Data

373 Participant	374 Exercise / Week	375 Sports	376 Ability (/ 10)	377 Jump Distance (m)	378 Jump Height (m)
375 1	376 4	377 soccer, tennis	378 6	379 2.3	380 1.1
376 2	377 2	378 soccer	379 7	380 2.5	381 0.8
377 3	378 3	379 -	380 2	381 1.6	382 1.0
378 4	379 4	380 ultimate frisbeez soccer	381 7	382 3.0	383 1.1

380 After running the full data processing pipeline, I generated the below correlation matrices, grouped by participant  
 381 and by sensor type 2.

383 Table 2. Force correlations for each participant by sensor type.

386 Participant	387 Avg Max Force (N)	388 Avg Height (m)	389 Flex Angle	390 Hall Effect Angle	391 Combined Angle	392 Acceleration
387 1	388 695.3	389 1.2	390 0.753	391 0.663	392 0.742	393 0.794
388 2	389 628.4	390 1.1	391 0.824	392 0.645	393 0.783	394 0.843
389 3	390 631.3	391 0.7	392 0.731	393 0.655	394 0.717	395 0.786
390 4	391 734.5	392 1.6	393 0.782	394 0.629	395 0.766	396 0.812
391 Average	392 672.4	393 1.2	394 0.773	395 0.648	396 0.752	397 0.809

398 The next table shows the correlation matrices with all sensor values normalized by acceleration and jump height 3.

399 Table 3. Force correlations of normalized data for each participant.

400 Participant	401 Avg Max Force (N)	402 Avg Height (m)	403 Flex Angle	404 Hall Effect Angle	405 Combined Angle
401 1	402 695.3	403 1.2	404 0.862	405 0.787	406 0.870
402 2	403 628.4	404 1.1	405 0.898	406 0.803	407 0.904
403 3	404 631.3	405 0.7	406 0.785	407 0.746	408 0.778
404 4	405 734.5	406 1.6	407 0.855	408 0.712	409 0.868
405 Average	406 672.4	407 1.2	408 0.850	409 0.762	410 0.855

411 Looking at the first table 2, the IMU average acceleration has the highest correlation with force. However, when the  
 412 sensor data is normalized by dividing by the jump height and acceleration, the correlation increases to be more than the  
 413 acceleration 3. This shows that the angular acceleration of your knee contains useful information that further explains  
 414 the characteristics of your jump, and can be used to improve an approximation of the force applied with the jump.

## 415 5 CONCLUSION

416 In conclusion, this experiment successfully showed, with a small sample size, that the force exerted when jumping can  
 417 be accurately estimated using a low-cost sensor system. Just using an accelerometer can produce somewhat accurate  
 418 Manuscript submitted to ACM

417 results, but when combined with knee angle data from either a flex sensor matrix or hall effect sensor, can produce the  
418 results needed for a good *Return to Play Protocol* test. Eliminating the need for a force plate has additional benefits. It  
419 enables anyone to easily conduct the *Return to Play Protocol* test, and allows for users to save a periodic benchmark to  
420 compare against. This would be particularly useful for athletes that are in high-knee impact sports, such as running,  
421 soccer and ultimate frisbee. However, this project was relatively limited in scope due to time constraints. Any future  
422 work would need to conduct the same experiment on more participants, collect more data, and verify the results.  
423

424 The data collection pipeline is done, but the user interface needs work, especially on the result display side. An  
425 important question that was not answered in this paper, is whether athletes would be willing to conduct these periodic  
426 benchmark tests, and save this data for when they get injured. Based on the number of injuries per year (see 1), it was  
427 assumed that athletes would invest the time if they are concerned, but this would be good to verify. Finally, we would  
428 recommend that future work be focused on how to leverage camera vision to improve the accuracy of this system even  
429 further. It would be interesting to explore if there is a way to classify the type of jump (whether users are jumping  
430 from with mainly their calves or quads, for example) and how that relates to force exerted. There are many avenues for  
431 further exploration, and it is definitely an exciting space to be in, with many meaningful questions to answer.
